ACKNOWLEDGMENTS

I wish to acknowledge here my indebtedness to those who have helped to make possible the completion of this study. Scores of teachers and school officers have coöperated with me in securing completion-test papers from over thirteen thousand public school pupils, and I am glad to record my obligation to them. It would be impossible to record here the names of all who have contributed thought and time to this investigation, but justice demands that I mention Professor E. L. Thorndike, whose example as an untiring scientific investigator and whose suggestive criticisms of this work as it has progressed have been of incalculable value. It would also be unjust not to mention my wife, without whose encouragement, and actual assistance in the monotonous mechanical work of scoring the results, this report would have been impossible.

M. R. T.

COMPLETION-TEST LANGUAGE SCALES

I

INTRODUCTION

This monograph is the report of an attempt to derive one or more scales for the measurement of ability along certain lines closely related to language. No attempt has been made to define "language" in any strict sense, and it is entirely possible that some persons may be able to speak the English language and perhaps to write it fairly well without being able to make a very high score on these scales. It may also happen that some individuals will be found who score well on these language scales and are yet unable to quote a single rule of English grammar. On the whole, however, it will be found that ability to complete these sentences successfully is very closely related to what is usually called "language ability."

Professor H. Ebbinghaus,¹ who invented the completion-test method, characterized it as "a real test of intelligence." It has been variously classified by psychologists, as a test of "imagination," as an "association test," as a test of "memory," and as a test of numerous other "faculties." As a matter of fact, the completion of incomplete sentences correlates remarkably well with almost any other measure of desirable qualities. It would perhaps have been just as descriptive to have used the classification "general stand-out-ish-ness" suggested by Professor Hollingworth;² but the obvious dependence of the ability to complete sentences upon the ability to read and think about printed words, and the magnitude of the correlations obtained between the completion test and other tests of language ability seemed to justify the classification of the completion-test scales for educational purposes as "language scales."

¹ H. Ebbinghaus: Ueber eine neue Methode zur Prüfung geistiger Fähigkeiten und ihre Anwendung bei Schulkindern. *Zeitschrift für Psychologie*, Vol. 13 (1897), pp. 401-459.

² H. L. Hollingworth and others: An Experimental Study of Self-Analysis, Estimates of Associates, and the Results of Tests. *School and Society*, Vol. II (1915), pp. 171-179.

One of the difficulties with the completion test has been that it was almost impossible to measure progress with it, because of the impossibility of finding two paragraphs of exactly the same difficulty. The story of a paragraph does not pass out of one's mind completely, and it is therefore not quite fair to say that better completion of the same paragraph at the second trial means improvement in ability. The scales presented in this study are made up of sentences dealing with a wide variety of subjects, none of which are very interesting in themselves, and as a rule they are forgotten comparatively soon. Because of this variety of subject matter and the careful gradation of the sentences, it will be possible to use the same scale upon the same children, after allowing a year or more for them to forget about it, without greatly invalidating the results. This will not be necessary, however, for Scales B, C, D, and E are for all practical purposes equal and interchangeable. Scales J and K are fairly well matched, and likewise Scales L and M differ very little in their difficulty.

Having the tests arranged as steps on a scale with approximately equal intervals between the steps offers several advantages over the paragraph-completion method. The individual being tested is not discouraged by having a task set for him which is beyond his powers, nor is he disgusted at having to do child's play. The first sentences are easy enough to encourage the youngest child who can read them, and the last sentences are hard enough to require thought of well trained persons. With these smaller sentence units it is also possible to get a more accurate judgment as to the quality of an individual's performance, and the comparison of two such performances is much more valid. It is very much easier and more accurate to judge that a sentence is "right," "almost right," or "wrong" than it is to judge that a paragraph is 20 per cent, 35 per cent, or 70 per cent "right." The average teacher finds it almost impossible to assign paragraph-completion scores which are quite comparable to the scores that a trained psychologist would assign to the same paragraphs. Very few teachers will be found, however, who can not use the scales proposed in this monograph and, with the assistance of the suggested scheme for scoring given in the Appendix, secure results which may be compared directly with the results obtained by other teachers in other school systems.

Allowing the same amount of time to all pupils, and giving each pupil two credits for each sentence perfectly completed and one credit for each sentence almost perfectly completed, automatically takes account of the time spent upon the work, the quality of the work done, and the difficulty of the tests one is able to do. An elaborate system of weighting might be used, but the results would probably be no more accurate than those obtained by this simple method of scoring. The consecutive tests are so well graded that (except in Scale A, the use of which || the writer does not recommend) there is only one chance out of four that any individual will complete a more difficult sentence without being able to complete those which precede it. If individual X can complete three sentences, individual Y four sentences, and Z five sentences on Scale D in the seven minutes allowed, we may feel fairly confident that X can complete the *first three*, Y the *first four* and Z the *first five* sentences, and that in ability to complete the sentences of Scale D, Z is as much better than Y as Y is better than X. In other words, with equal distances between steps, the same number of points score may be assigned for each step taken, without distorting the facts, for the score is cumulative. (

II

LANGUAGE SCALE A

I. HISTORY OF ITS DERIVATION

During April, May, and June, 1914, the writer tested 855 pupils in two public schools of New York City with a "preliminary list" of fifty-six completion-test sentences. The results obtained indicated that a few of the sentences of this preliminary list were so constructed as to have little value as completion tests for children, and that, after rearranging the sentences in the order of their difficulty, there were a few places in the list where gaps occurred between consecutive sentences.

By throwing aside the poorly constructed sentences of the preliminary list, arranging the remainder according to their difficulty for the 855 children who had tried them, and attempting to write other sentences to fill the gaps found in the preliminary list, a second list of fifty-six sentences was prepared. This second list of fifty-six completion-test sentences will be referred to in this monograph as "The Graded Series."¹

With the Graded Series of tests the writer tested, during the last two months of 1914 and the first month of 1915, over five thousand children in the public schools of New York and New Jersey. On the basis of these results, two sentences of the Graded Series were selected for each school grade, the two being selected for each grade which had proved to be just difficult enough to be done by about 50 per cent of the children in that grade. This list of twenty-four selected completion tests has for convenience been called "Language Scale A."² Scale A therefore contains two second grade sentences, two third grade sentences, and so on up through the eighth grade and high school, ending with two sentences which had proved so difficult that a rather small percentage of the first year college class had been able to complete them.

¹ This list was presented by the writer at the meeting of Section L of the American Association for the Advancement of Science, Dec. 31, 1914, at Philadelphia.

² Scale A was reported in *School and Society*, April 10, 1915, under the title, "Some Results of a Graded Series of Completion Tests."

2. SCALE A, ITSELF

On each line of dots, write the word which makes the best meaning

ONLY ONE WORD ON EACH BLANK

II

- x. The sky blue.
y. We are going school.

III

- x. The kind lady the poor man a dollar.
y. The plays her dolls all day.

IV

- x. Time often more valuable money.
y. Boys and soon become and women.

V

- x. The poor baby as if it were sick.
y. The rises the morning and at night.

VI

- x. It is good to hear voice friend.
y. She if she will.

VII

- x. The poor little has nothing to; he is hungry.
y. The boy who hard do well.

VIII

- x. Men more to do heavy work women.
y. It is a task to be kind to every beggar for money.

IX

- x. Worry never improved a situation but has made conditions
y. A home is merely a place one live comfortably.

X

- x. It is very to become acquainted persons who timid.
y. To many things ever finishing any of them a habit.

XI

- x. One's real appears often in his than in his speech.
y. When one feels drowsy and, it happens that he is to fix his attention very successfully anything.

XII

- x. The knowledge of use fire is of important things known by but unknown animals.
y. that are to one by an friend should be pardoned readily than injuries done by one is not angry.

XIII

- x. To friends is always the it takes.
y. One ought to great care to the right of, for one who bad habits it to get away from them.

3. REPORT OF SCORES MADE ON SCALE A

During the months of April, May, and June, 1915, over six thousand children and young people spent fifteen minutes each in an attempt to complete the sentences of Scale A, as shown above. In those cases where a third page of sentences was added, enough more time was allowed to enable each individual to have a reasonable amount of time for each sentence. The majority of the classes tested were in the schools of New York and New Jersey, although records were obtained from a number of classes in Illinois, Indiana, Michigan, Missouri, and Pennsylvania.¹ The results from these other states indicated that there was no great difference in the abilities of children in the same grade in different states, so that the measurements here reported may be taken as fairly representative of conditions in general.

The detailed scheme by which each sentence was scored will be found in the Appendix, but in order that the reader may understand what is meant by the score, a word of explanation will be given here. Each sentence which the pupil had the opportunity to complete was given a score of 2 if perfectly completed, a score of 1 if almost but not quite perfectly completed, and a score of 0 if not attempted at all or if imperfectly done. The child who successfully completed two sentences in Scale A would therefore receive a score of 4, or 2 points for each sentence. If he had completed three sentences perfectly and a fourth very nearly perfectly, his total score would be 7 points. In this way anyone who did all the twenty-four sentences of Scale A perfectly in

¹ In these cases it was impossible for the writer himself to give the tests, although there is every reason to believe that the results are fully comparable to those given by him personally. The classes chosen in these states were in each case chosen because of the principal's training and understanding of scientific testing, and detailed instructions were given each principal in order to secure exactly comparable results. All of the papers were scored by the same detailed scheme, which was prepared by the writer and will be found in the Appendix. All papers were scored either by the writer or by his wife, except in the case of some of the papers of the preliminary list on which some assistance was given by one other individual.

In the New York and New Jersey classes the writer hired substitute teachers to assist him in keeping time and collecting papers. He would instruct these assistants and train them so that they knew just what to do. He would then go to a class room, explain the test to the children, start them to work, and leave one of these assistants to collect the papers while he went to another room, where the same procedure was followed. In this way he was able with three assistants to obtain records from a large number of children in a short time. In a few instances these trained assistants were allowed to take complete charge of the administration of the tests after they had become thoroughly familiar with the process.

fifteen minutes would receive a total of 48 points, which is the maximum possible score in Scale A.

In addition to the six thousand individuals who tried Language Scale A in the form given above, I have gone through the records of the five thousand who tried the Graded Series, from which Scale A was selected, and have found the total score made by each individual in the twenty-four sentences of Scale A. The results from these two groups vary little and are combined in Table I, which shows the distribution of scores made by the pupils of each elementary school grade. Beginning at the lower left-hand corner, Table I indicates that a score of 0 was made by 255 of the 1318 pupils in the second grade, by 19 of the 1437 pupils in the third grade, and by 1 of the 1463 pupils in the fourth grade. Table I not only shows the number of pupils in each grade who made each score, but it also shows the median score, or the score made by the middle pupil of the grade if all the pupils of the grade were arranged in order according to the ability each exhibited in this test. In addition, Table I gives the range of score that would be necessary in each grade to include half of all the children in the grade, and the quartile, which is half of the range of the middle 50 per cent and will serve as a useful measure of the variability.

Quartile	2 085	3 413	4 157	3 614	3 610	3 750	4 041

Medians and percentiles should not be worked out to the third decimal point in ordinary practice. Reporting the median to the nearest whole number or to the nearest tenth of a whole number will be better when dealing with Scale A, for reporting to the third decimal suggests a refinement of measurement to which Scale A can lay no claim, except in cases where large numbers of individuals have been measured, as in the case of Table I.

For those interested in the measurement of classes, Table II has been prepared, showing the distribution of median class scores in the elementary grades. As would be expected, the median of the class medians is very nearly equal to the median score of all children tested in any given grade.

of graduate students in Educational Administration at Teachers College. This last group was used simply as a group superior to high school seniors.

4. CRITICISM OF SCALE A

It will be noticed as one glances up through the grades that each successive grade makes a higher score than the grade just previous and that the range of the middle 50 per cent likewise moves steadily upward. This is, of course, to be expected, although the relative amounts of progress between grades are unusual and need to be examined more carefully. The crude score intervals between grade medians are, according to Table I, roughly as follows:

Grades	II-III	III-IV	IV-V	V-VI	VI-VII	VII-VIII
Interval	4.4	5.3	4.1	3.5	3.4	2.8

There is no good reason for thinking that greater progress is made between the third and fourth grades than between the second and third, and careful examination proves that this relatively large advance between the third and fourth grades is due to imperfections in Scale A. If it had been possible, in the selection of the sentences for Scale A, to select two sentences of exactly "median" or 50 per cent difficulty for each grade, and then if the pupils tested later had performed exactly as those tested previously, there would have been a distinct tendency toward the equalization of the score intervals between grades, although the intervals would still have decreased in passing to higher grades. As it happened, the second grade sentences were distinctly too easy (59%, 58%); the third grade sentences too hard (46%, 46%); and the fourth grade sentences were practically 50 per cent sentences (50%, 54%). As a result, the third grade did not have as much of a chance to show superiority over the second as the fourth had over the third.

In a later section of this study the relative distances between grades are calculated to be about as follows:

Grades	II-III	III-IV	IV-V	V-VI	VI-VII	VII-VIII
Interval ¹	1.6	1.2	.9	.8	.8	.6

¹ The unit upon which these intervals are calculated is the P.E., or the median deviation from the median of a grade distribution. This is explained in greater detail in the section headed "Normal Surface of Frequency Assumed" (p. 30-35), but for the present it may be thought of as a rather accurate unit of measurement which has the same value in all grades.

Fig. 1 gives a graphic comparison of the relations of the medians of the various school grades tested, measured first by the crude score on Language Scale A and second by the average of three determinations of the P.E. intervals.

FIG. 1. Comparison of the Inter-Grade Intervals Obtained from Crude Score in Scale A with Those Obtained Statistically. Each circle above the line represents the position of the median of a school grade distribution on the scale shown below the line.

Although the relative positions of the grades are in many respects similar in the two projections shown above, the crude score on the Language Scale is clearly not sufficiently accurate to be used alone. An arrangement of the sentences of Scale A on a linear projection similar to the second in Fig. 1 shows how imperfectly Scale A is constructed.

FIG. 2. Linear Projection of the Difficulty of the Sentences of Language Scale A.

A perfect scale for any function as complex as that tested by language completion tests would be very difficult to construct, although the scales presented in the next section of this report are far superior to Scale A in some particulars. It would be very convenient to have a scale in which each step was perfectly defined and exactly one unit more difficult than the step preceding it, but to secure such a scale would require an enormous amount of time and labor, and the advantage gained over a scale which approximates those conditions would be slight. A glance at Fig. 2, however, shows that there would be great improvement in Language Scale A if another step were introduced between sentences 2 and 11 and if some of the sentences between 6 P.E. and 9 P.E. were omitted. The positions of the various school grade medians on the crude score projection in Fig. 1 indicate the same difficulty in Scale A.

5. SUGGESTIVE RESULTS OF ITS USE

In spite of the inequalities that occur in the steps on Language Scale A, it has shown some rather interesting possibilities. There is a very general conviction among teachers that girls have greater ability along language lines than boys. I have gone through my records of sixth grade children and tabulated the scores of 1224 of them according to sex and age.¹ The results are shown in Table IV.

On the whole, it appears from Table IV that boys make a somewhat lower median score than girls in the same grade, although the difference is small and the amount of overlapping is enormous. A small sampling from the other elementary grades indicated that the same conditions hold true there, so the facts shown in Table IV may be taken as fairly typical. It is interesting to note that there is a rather distinct tendency for the older pupils in the grade to make lower scores than those younger. This suggests that teachers are possibly inclined to promote dull pupils because of their age and to retard the bright pupils because of their youth. However that may be, Table V makes it pretty clear that ability counts for a great deal more than age in determining promotion.

In view of all that has been said recently concerning the inability of teachers to judge the abilities of their pupils and to promote them accordingly, the facts shown in Table V are rather surprising. To say that a child is twelve years old apparently signifies far less concerning his ability to complete sentences than to say that he is in the sixth grade. The variability of the sixth grade, if the quartile is taken as a measure, is only about 73 per cent of the variability of the twelve-year-olds. The median score of each grade group of twelve-year-old children is remarkably near the median score shown in Table I for all children in that grade group. There is undoubtedly a very close relation between the criteria used by teachers in promoting pupils and the abilities required to complete mutilated sentences.

To measure progress in individual pupils and classes should be one of the uses of a good scale. In one school where the writer had given the Graded Series in November, 1914, the superin-

¹ This tabulation was made before all of the results were available, and therefore the total number of sixth grade children in this tabulation is smaller than the total shown in Table I.

Table VI indicates that 11 boys and 4 girls in the eight-year-old group made exactly the same score in June as in November, while one boy and two girls made one point more in June than in November, etc. It is interesting to note that some of the twelve-year-old children actually made poorer scores in June than they had made in November.

tendent gave Language Scale A in June, 1915. The mid-year promotions which intervened had distributed the class groupings so that it was impossible to measure the progress of classes. The writer, however, searched out the November records of a group of eight-year-old children and of a group of twelve-year-old children to determine what score each of these children had made on the twenty-four sentences of Scale A. This record for each individual was then compared with his June record in Scale A,

and any change of score was recorded. Table VI shows the changes that were found. The superintendent had emphasized the language work throughout the year on account of the poor showing made in November, so that the amount of progress shown in Table VI is possibly somewhat larger than would ordinarily be found.

As we have already seen, the steps on Scale A are not equal in length. An improvement of ten points score may therefore mean something entirely different to two individuals, one of whom improves from 5 to 15 and the other from 20 to 30. For this reason the facts shown in Table VI are of little value, except as an illustration of how improvement may be measured now that we have scales on which the consecutive steps are equal.

III

ADDITIONAL LANGUAGE SCALES

I. USE OF SHORT SCALES

Although Language Scale A has proved itself a rather useful instrument, it has seemed best to arrange a number of shorter scales in which the intervals between steps are more nearly equal. It often happens that an individual does not feel "at his best" on certain days and, whether his level of performance is actually lower or not, at such times he feels that it is an injustice to him to have his ability judged on the basis of his "off day" performance. Measurements of individuals made for the purpose of obtaining correlations between tests are more useful if made at two or more different times with equal tests, for such a procedure allows one to make some very desirable corrections for the attenuation due to chance inaccuracies in the measures. Evidence from two or more measurements of the same individual becomes cumulative and convincing, while a single measurement may be overlooked as not significant. In fact, the amount of difference between the two measurements will often be taken as a rough indication of the reliability of the measurements. For these and other reasons the writer recommends that in measuring individuals two short scales be used rather than one long scale.

Although it will always be advisable to use more than one of the short scales when an accurate measurement of an individual is desired, a class may be measured fairly well by means of a single scale. The chance inaccuracies in the measurement of an individual, whereby a single measurement gives him credit for more or for less ability than he deserves, tend to be balanced by inaccuracies in the opposite direction from the measurements of other individuals when a group is being measured. Improvement in a class may be measured by comparing the median score made by the class on one scale with the median score made by the class at a later date on another scale of the same difficulty, or even better by comparing the total distribution on one scale with the total distribution on the other equal scale.

2. SCALES B AND C

- Language Scales B and C are chosen entirely from the carefully evaluated sentences of the Graded Series and the writer feels a great deal of confidence in them. Each of these two scales
- consists of ten steps or sentences, each step being about 1 P.E. above the previous step. Scale C, however, is on the whole about .4 P.E. more difficult than Scale B. These two scales are as follows:

Write only one word on each blank.

Time limit, seven minutes.

Name

LANGUAGE SCALE B

1. We like good boys girls.
6. The is barking at the cat.
8. The stars and the will shine tonight.
22. Time often more valuable money.
23. The poor baby as if it were sick.
31. She if she will.
35. Brothers and sisters always to help other
and should quarrel.
38. weather usually a good effect one's spirits.
48. It is very annoying to tooth-ache, often
comes at the most time imaginable.
54. To friends is always the it takes.

Write only one word on each blank.

Time limit, seven minutes.

Name

LANGUAGE SCALE C

2. The sky blue.
5. Men older than boys.
12. Good boys kind their sisters.
19. The girl fell and her head.
24. The rises the morning and at night.
30. The boy who hard do well.
37. Men more to do heavy work women.
44. The sun is so that one can not
directly causing great discomfort to the eyes.
53. The knowledge of use fire is of
important things known by but unknown animals.
56. One ought to great care to the right of
....., for one who bad habits it to
get away from them.

The exact difficulty of each sentence in Scales B and C, with the intervals between consecutive steps, is shown in Table VII.

TABLE VII

STEPS AND INTERVALS BETWEEN STEPS ON SCALES B AND C. 1 = P.E.

Language Scale B			Language Scale C		
Sent. No.	Value	Interval	Sent. No.	Value	Interval
1	.96		2	1.38	
6	1.98	1.02	5	2.52	1.14
8	2.94	.96	12	3.58	1.06
22	4.26	1.32	19	4.47	.89
23	5.40	1.14	24	5.69	1.22
31	6.50	1.10	30	6.95	1.26
35	7.42	.92	37	7.85	.90
38	8.42	1.00	44	8.95	1.10
48	9.50	1.08	53	10.05	1.10
54	10.76	1.26	56	11.17	1.12

The same facts are shown graphically in Fig. 3.

FIG. 3. Linear Projection of Language Scales B and C.

Exactly seven minutes of actual work should be allowed any individual on either of these two scales. In testing school children, the procedure outlined below should be carefully followed in order that all measurements may be exactly comparable.

3. DIRECTIONS FOR ADMINISTERING TESTS

If the class to be tested is a fourth grade class or higher, oral explanations will be sufficient. Below the fourth grade it will be necessary to distribute to each pupil the following practice

list, before allowing any pupil to see the scale with which he is to be measured.

Practice Sheet

Two and two are
A boy is little, but a man is
Girls and boys can run play.
The boy has book.

After passing one of these practice sheets to each child, make the following general explanations:

I want to see if you can read what is printed on the little sheet of paper, and whether you can guess what words have been left out. Each little dotted line shows where a word was left out. If you can guess what word ought to be there, write it on the dotted line. Write just one word on each blank. Make each line say something.

After making the above explanation, the teacher and the examiner should give assistance to any child who does not understand, seeing that each child learns what is expected.

After the examiner is confident that each child has the correct idea of how to proceed, a copy of the scale to be used should be held up in full view of the entire class and the statement made that "This page is very much like the little sheet on which you have just been working, except that the last sentences on this sheet are very much harder." From this point the procedure is practically the same as that for the higher grades.

In the fourth grade or above, or after the preliminary practice just described has been completed in a lower grade, the following oral explanation of the scale to be used should be made before distributing any papers:

This sheet contains some incomplete sentences, which form a scale. This scale is to measure how carefully and rapidly you can think, and especially how good you are in your language work.

You are to write one word on each blank, in each case selecting the word which makes the most sensible statement.

You may have just seven minutes in which to sign your name at the top of the page and write the words that are missing. The papers will be passed to you with the face downward. Do not turn them over until we are all ready. After the signal is given to start, remember that you are to write just *one* word on each blank and that your score depends on the number of perfect sentences you have at the end of seven minutes.

If there are no questions, the papers may then be distributed, taking care that no child looks at the printed side until there

is a paper upon the desk of each child and the following additional instructions have been given:

After you have been working seven minutes, I shall say, "The time is up. All stop writing!" You will all please stop at once and lay aside your pens (or pencils). Now if you are all ready, you may turn your papers, sign your names and fill the blanks.

Take note of the exact time at which the signal to start was given, allow exactly seven minutes, and give the command to stop writing. Collect all papers at once. It is very important that exactly seven minutes be allowed. A stop watch is the most satisfactory means of keeping the time on a test of this sort.

Grade each paper according to the scheme shown in the Appendix of this monograph, and make a record of the total number of points made by each child, in order that the amount of progress made by each pupil may be readily determined when the scale is used the second time. (It would be advisable not to use the same scale again until a year or more has passed. Use a different scale of the same difficulty.)

To calculate the median score of a class follow the directions given in Section 3 of the Appendix.

4. SCALES D AND E

Language Scales D and E are practically of the same difficulty as Scales B and C. Scales D and E, however, each contain four sentences which were not a part of the Graded Series,¹ and although these two scales will be found very satisfactory, it is entirely possible that the difficulty of any one of the eight sentences referred to may differ as much as .3 or .4 P.E. from the value I have assigned to it. As a matter of fact, the course of this investigation has shown that the difficulty of a test sentence is influenced rather markedly by the number and character of the sentences near it. This does not, however, invalidate the scale; it merely indicates that the final value of each step on a scale of this kind cannot be determined accurately until thousands of children of all grades have attempted the scale in its final form. Indeed, it is questionable whether the utilities added by knowing so accurately the final value of each step would

¹ All sentences numbered from 1 to 56 were in the Graded Series and, as will be found from reading Chapter IV of this monograph, the difficulty of each of them has been very well defined. The difficulty of all sentences numbered above 56 has been estimated as carefully as possible.

be of sufficient practical importance to pay one for the labor of making the determination.

Language Scales D and E are as follows:

Write only one word on each blank.

Time limit, seven minutes.

Name

LANGUAGE SCALE D

4. We are going school.
76. I to school each day.
11. The plays her dolls all day.
21. The rude child does not many friends.
63. Hard makes tired.
27. It is good to hear voice friend.
71. The happiest and contented man is the one lives a busy and useful
42. The best advice usually obtained one's parents.
51. things are satisfying to an ordinary than congenial friends.
84. a rule one association friends.

Write only one word on each blank.

Time limit, seven minutes.

Name

LANGUAGE SCALE E

73. I see you. Can you see?
75. Ice is cold, but fire is
7. The kind lady the poor man a dollar.
18. The best to sleep is at night.
58. Children should many lessons from parents.
25. The child the river was drowned.
34. It is a task to be kind to every beggar for money.
36. Worry never improved a situation but has made conditions
52. When one feels drowsy and, it happens that he is to fix his attention very successfully anything.
83. In order clearly at it is to artificial

The difficulty of each sentence in Scales D and E is shown in Table VIII.

TABLE VIII

STEPS AND INTERVALS BETWEEN STEPS ON SCALES D AND E. 1 = P.E.

Language Scale D			Language Scale E		
Sent. No.	Value	Interval	Sent. No.	Value	Interval
4	1.00		73	1.18	
		.97			.45
76	1.97		75	1.63	
		1.34			1.71
11	3.31		7	3.34	
		1.09			1.08

		1.22			1.01
42	8.86		36	8.32	
		.92			.97
51	9.78		52	9.29	
		1.07			1.26
84	10.85		83	10.55	

Fig. 4 represents the same facts in a graphic way.

FIG. 4. Linear Projection of Language Scales D and E.

It will be observed that Scale E is somewhat more irregular and has a slightly shorter range than Scale D. The lower end of Scale E is a bit more difficult than the lower end of Scale D, while Scale D is the more difficult in the upper ranges. In spite of these differences, these two scales may ordinarily be used as though they were equal to each other and to Scales B and C.

The instructions given above for the administration of Scales B and C apply equally well to these two scales.

5. SCALES J AND K

Scales J and K are intended to measure the abilities of young people and adults rather than of children. The time to be allowed is exactly five minutes for each of the scales, although the general procedure described above for Scales B and C should be followed in their administration. The intervals between steps in these two scales are intentionally made long, the upper steps are very high, and there are no sentences easier than 4. P.E. Care should be taken not to confuse Scales J and K with any other scales, for each of these two is equal to the other only.

Language Scales J and K are as follows:

Write only one word on each blank.

Time limit, five minutes.

Name

LANGUAGE SCALE J

29. Boys and soon become and women.
 61. The are often more contented the rich.
 64. The rose is a favorite because of fragrance and
 41. It is very to become acquainted persons who timid.
 93. Extremely old sometimes almost as care as
 87. One's in life upon so factors it is not to state any single for failure.
 89. The future of the stars and the facts of history are now once for all, I like them not.

Write only one word on each blank.

Time limit, five minutes.

Name

LANGUAGE SCALE K

16. The boy will his hand if plays with fire.
 57. Hot weather comes in the and weather the winter.
 28. The poor little has nothing to; he is hungry.
 33. Very few people how to spend time and to the best advantage.
 82. One not, as a, attention uninteresting things.
 90. To eat one is is a pleasure.
 86. they us not, nature's are and unchangeable.

Table IX shows the values that were obtained for each sentence in Scales J and K.

TABLE IX

STEPS AND INTERVALS BETWEEN STEPS ON SCALES J AND K. 1 = P.E.

Language Scale J			Language Scale K		
Sent. No.	Value	Interval	Sent. No.	Value	Interval
29	4.12		16	4.15	
		1.73			1.83
61	5.85		57	5.98	
		1.17			1.06
64	7.02		28	7.04	
		1.35			1.34
41	8.37		33	8.38	
		1.16			1.18
93	9.53		82	9.56	
		1.22			1.23
87	10.75		90	10.79	
		1.56			1.86
89	12.31		86	12.65	

Fig. 5 is a linear projection showing the positions of each sentence of Scales J and K on the P.E. scale.

FIG. 5. Linear Projection of Language Scales J and K.

The value obtained for each sentence in Scale K is remarkably near the value obtained for the corresponding sentence in Scale J. The possibility that some of these values may shift when tried out on thousands of individuals is, however, even greater than in the case of Scales D and E. The values given in Table IX are nevertheless the most accurate obtainable at present and may be used with confidence until more exact values have been established. Scales J and K are unquestionably the most equally matched pair of completion tests for measuring young people and adults that have yet been obtained in the English language.

6. SCALES L AND M

For the measurement of smaller differences in the abilities of secondary school pupils, I have arranged Scales L and M, which begin at about 7 P.E. and progress by relatively small steps to over 11 P.E. These are also five-minute tests. It is believed that they will be found very valuable to secondary school teachers and others interested in the abilities of young people.

The sentences composing Language Scales L and M are given below.

*Write only one word on each blank.
Time limit, five minutes.*

Name

LANGUAGE SCALE L

IV

CALCULATION OF THE DIFFICULTY OF TEST SENTENCES

I. VARIABILITY OF A GRADE AS THE UNIT

The comparison of adjectives is a device used by all people to denote different *amounts* of qualities. When one makes the judgment that John is "brighter" than Joe, he has made a rough measurement of the amount of the quality termed "brightness" possessed by these two boys. If everyone knew John and Joe and their relative brightness, and if these two boys maintained exactly the same degrees of that quality from the present time forward, John and Joe might serve as a rough scale for brightness. It would then be possible to say that James has "the brightness of John" with some assurance of being understood. The difficulty with such an arrangement is that John and Joe both change in brightness and at different rates. It is also impossible for everyone to know these two boys, and therefore they cannot be of very wide service as a brightness scale. Any scale that is to be of much service must be built of units the amounts of which remain constant and in such form that they can be readily examined by anyone interested or verified by any competent person.

It would be possible to build up a completion-test scale by merely selecting a series of sentences which the majority of a group of people agreed upon as arranged in the order of their difficulty. Or, one might select as a scale a series of sentences which had been tried upon a group of children and found to be so arranged in the order of their difficulty that each consecutive sentence was correctly completed by just 10 per cent of the group less than had completed the previous sentence. Such scales would no doubt be much more useful than an entirely ungraded series of sentences. Unless the above scales were based upon a firmer foundation than I have indicated, however, it would perhaps be found that a second group of judges would disagree with the first group in regard to a few of the sentences, and that a second

group of children would show percentages entirely different from the first, possibly to the extent of showing no more than 20 per cent difficulty between the hardest and the easiest sentences in the series, which with the previous group had a range of 100 per cent. There is need for some less changeable unit than uncertain majorities or percentages of variable groups.

One of the most constant things about a variable fact is the amount of its variability. One's accuracy as a judge of any quality remains fairly constant, and the accuracy of one group of judges very nearly equals the accuracy of any other similarly chosen group.

The variation in the abilities of the children in one group is about equal to the variation in the abilities in any other group of children chosen in the same way. Teachers select their brightest pupils for promotion and refuse to promote the dullards. Now the abilities of teachers to make this selection is about the same in one school system as it is in another, and about the same in eighth grade teachers as it is in second grade teachers. As a result, one school grade may differ quite markedly from another in ability and yet the amount of variability in one will be very nearly equal to the amount of variability in the other. If one desires to make a scale for use in all grades, then, it would seem desirable to use some measure of the variability of a grade as the unit, since this is at once common to all grades and only slightly variable in itself.

2. NORMAL SURFACE OF FREQUENCY ASSUMED

Before choosing any particular measure of the variability of a grade to be used as a unit of measurement, it will be valuable to discover how the "completion-test ability" is distributed in each grade. If this ability is distributed in the same way as the abilities by which teachers judge to what grade a child belongs, we should expect to find most of the children in any given grade clustered about the average or median for that grade. We should not expect to find that teachers always make perfect judgments as to promotions, but we should expect to see fewer large errors than small ones. In short, we should expect to find the abilities of the children in any given grade distributed symmetrically on each side of the average, as shown in Fig. 7.

FIG. 7. Symmetrical Form of Distribution of Abilities to be Expected of Children in Any Given Grade.

The height of the curve above the base-line indicates the number of individuals in the class having the ability shown on the base-line scale. Each individual is represented by an equal amount of the total area inclosed by the curve and the base-line.

Assuming that Language Scale A is a reasonably valid measuring instrument for the completion-test ability, Figs. 8 to 14 show how this ability was distributed in the 1400 children of each elementary grade tested by the writer.¹ Except in the second and third grades,² the curves are remarkably symmetrical and regular, conforming on the whole to the general characteristics of the normal surface of distribution shown in Fig. 7.³ All the evidence at hand leads us to believe that the distribution of the abilities measured by the completion test conforms to this shape in each grade, and it will therefore be assumed throughout the remainder of this study.

Assuming the normal surface of frequency, then, the Median Deviation or P.E. from the median will be the most convenient measure of the variability to use as a unit. Of course one might use the distance between the best and the poorest individuals in the class as a measure of the variability, but this would give such a large unit that the scale would be practically useless as a measure of small differences. Another reason for not using the extreme range of the distribution as a measure is the fact that the few very poor individuals and the few very good individuals in each grade would have more influence over the size of the unit than all the hundreds of average children in the grade.

¹ The data upon which Figs. 8 to 14 are based are shown in Table I.

² The excessive height of the columns for scores of 0, 2, 4, 6 and 8 in the second and third grade figures is due to the peculiarities of the method of scoring, in that 2 points score were given for each perfect sentence and 1 point for each partially perfect sentence. The children in these lower grades as a rule either get the sentence perfect or not at all.

³ This fact in itself is not conclusive proof that completion-test ability is distributed according to the normal surface of distribution. Better proof is found in the fact that if this assumption is made the results that follow are in such close accord with known facts.

FIG. 3. Distribution of Scores Made by Second Grade Pupils on Scale A.

FIG. 4. Distribution of Scores Made by Third Grade Pupils on Scale A.

FIG. 5. Distribution of Scores Made by Fourth Grade Pupils on Scale A.

FIG. 11. Distribution of Scores Made by Fifth Grade Pupils on Scale A.

FIG. 12. Distribution of Scores Made by Sixth Grade Pupils on Scale A.

FIG. 13. Distribution of Scores Made by Seventh Grade Pupils on Scale A.

FIG. 14. Distribution of Scores Made by Eighth Grade Pupils on Scale A.

The median deviation is the median amount of deviation, whether the deviations are above the median of the distribution or below. If all the children in the grade were arranged in order according to their distance from the median along the base-line scale, we might begin at the median and count out just one half of the children. The distance along the base-line covered in counting out half of the children would be the median deviation.

FIG. 15. Lower Half of a Normal Surface of Frequency.

Fig. 15 shows the lower half of a normal surface of frequency, with a line drawn perpendicular to the base in such a way as to cut off just one half of the area below the median. Half of the deviations represented by the total area shown are greater than line BD and half of them are less than line BD. BD is therefore the median deviation from the median, or the P.E., as it will be called for convenience in this study.

Since the normal surface of distribution is perfectly symmetrical, the area ABC shown in Fig. 15 represents just one half or 50 per cent of all the individuals represented by the total surface. Since area DBCE is just one half of area ABC it must contain one fourth or 25 per cent of the total number of individuals. If one draws a line perpendicular to the base at a point 1 P.E. below the median of a normal surface of distribution, he will always divide the lower half of the distribution into two equal parts, each of which contains 25 per cent of the total distribution. Drawing a line 1 P.E. above the median would likewise divide the upper half of the distribution into two equal parts, each containing 25 per cent of the total area.

The characteristics of a normal surface of distribution have been very carefully worked out. We know that the middle 50 per cent of any such surface is contained within the limits -1 P.E. and $+1$ P.E. We know that if we start from the median of the distribution and go 1 P.E. in either direction, a perpendicular line

FIG. 16. Normal Surface of Frequency, with P.E. Distances from Median.

to the base at that point would so divide the distribution that 25 per cent of all frequencies would lie between that line and the median; if we pass on to a point 2 P.E. from the median, 41.13 per cent of the cases would lie between the perpendicular and the median; at 3 P.E. from the median, 47.85 per cent of all cases are between the perpendicular and the median; and at 4 P.E. from the median, 49.65 per cent of the surface lies between the perpendicular and the median. Theoretically, the curve and the base-line do not meet but continue to approach each other as the distance from the median becomes greater. For practical purposes, however, we may consider that they meet at about 4.6 P.E. from the median, for a perpendicular drawn here cuts off only 0.1 per cent of all the surface.

3. SCALING THE SENTENCES OF SCALE A FOR EACH GRADE

Having adopted the P.E. of a grade as the unit of measurement, and having assumed that the normal surface of frequency represents the distribution of completion-test ability in any given grade, we may now attempt to arrange our sentences upon a P.E. scale for each grade.

Table XI gives the total number of points score made in each elementary grade upon each sentence of Language Scale A, and the score that would have been made on any given sentence if every child in a grade had succeeded in completing it perfectly.

Table XI indicates that Sentence No. 2, "The sky..... blue," was given 1798 points out of a possible 2636 in the second grade, 2597 out of a possible 2874 points in the third grade, etc. Turned into per cents, sentence No. 2 made 68.21 per cent of the total score possible for it in the second grade, 90.36 per cent in the third grade, etc. Since the number of children tested was different in each grade, it will be necessary thus to reduce all scores to percentages in order that the surfaces of distribution may all be of the same area. The scores shown in Table XI are given in percentages by Table XII.

TABLE XI

SCORE MADE BY EACH ELEMENTARY GRADE ON EACH SENTENCE OF LANGUAGE SCALE A

Sentence No.		Grade II	Grade III	Grade IV	Grade V	Grade VI	Grade VII	Grade VIII

		*1029						
Perfect Score		2636	2874	2926	3014	2908	2912	2854
		*2058						

A sentence like No. 36, which no one of the 1318 children in the second grade was able to complete, is very evidently too difficult for second grade pupils. Just how much too difficult it is we do not know, but if we assume the normal surface of frequency we know that it is more than 4.6 P.E. above their median, for if it were nearer to the second grade median than that distance, it would probably have received a score in this grade. As it is, the entire surface of the second grade distribution lies below sentence No. 36. A sentence receiving a score of 25 per cent in the second grade would be just 25 per cent or 1 P.E. too difficult for

TABLE XII

PER CENT THAT SCORE MADE BY EACH ELEMENTARY GRADE IS OF PERFECT SCORE FOR EACH SENTENCE OF LANGUAGE SCALE A

56	13y				.14	.38	1.21	3.61

the median second grade pupil. Sentence No. 2, which received a score of 68.21 per cent in the second grade, is just 18.21 per cent too easy ($68.21 - 50.00 = 18.21$) for the median child in this grade. Reference to Table XIII,¹ which gives the P.E. values of each tenth of a per cent from 0.0 to 49.9 above or below 50 per cent, indicates that 18.21 per cent difference is equal to .702 P.E. We may therefore locate sentence No. 2 with reference to the second grade median as at $-.702$. Sentence No. 4, having a 69.57 per cent score, is just 19.57 per cent too easy ($69.57 - 50.00 = 19.57$) for the median second grade child, and reference to Table XIII locates the sentence at a distance of .759 P.E. from the median. Since it is too easy for the median child, the sentence will be below the second grade median, or exactly $-.759$.

¹ Table XIII is taken directly from B. R. Buckingham's *Spelling Ability* (Table XLVII). It is a modification of the table given in E. L. Thorndike's *Mental and Social Measurements* (page 200).

TABLE XIII

P.E. VALUES CORRESPONDING TO GIVEN PER CENTS OF THE NORMAL SURFACE OF FREQUENCY, PER CENTS BEING TAKEN FROM THE MEDIAN

Table XIV shows the differences between 50 per cent (or the grade median) and the percentages given in Table XII. Table XV shows the P.E. equivalents of these differences shown in Table XIV, or the location of each sentence of Scale A with reference to the median of each elementary grade.

56	13y				-49.86	-49.62	-48.79	-46.39

The figures shown in Table XV form for each elementary grade the final measure of the difficulty of any given sentence for that grade. If it were not desirable to show the difficulty of each sentence for all grades together, we might use the values of Table XV without making any further changes in them. Indeed, if any person desires to know the difficulty of any sentence in Scale A for the fifth grade or for any other elementary grade, Table XV gives the necessary data.

The measurement of the difficulty of these sentences in the

higher grades is made in exactly the same manner as it was made in the elementary grades: the score on each sentence is turned into percentages of the perfect score, the differences between these percentages and 50 per cent being then turned into P.E. differences by means of Table XIII. This assumes, of course, that ability to complete sentences is distributed according to the normal surface of frequency in each higher grade. The score and the P.E. distances from the medians are given in Table XVI for the eighth grade and high school classes in those school systems where the writer was able to test both the elementary and high school classes. The same facts are shown for the group of graduate students at Teachers College.

4. MEASUREMENT OF THE DISTANCES BETWEEN GRADES

There are a number of ways in which the P.E. distances between consecutive grades can be measured. Three methods have been used in this study and the average of the three has been taken as the most probably true measure of the distance in each case.

We have assumed that the ability to complete sentences is distributed in any given grade in accordance with the normal surface of frequency. The assumption was also made, although it was not clearly stated, that each sentence to be completed is a test of ability to complete sentences, and that ability to complete individual sentences is distributed "normally." The difference between two consecutive grades may therefore be measured by the difference in the positions with reference to the two grade medians held by any given sentence. For example, sentence

No. 2 was, according to Table XV, .702 P.E. below the second grade median and 1.931 P.E. below the third grade median, which makes a difference of 1.229 P.E. between the medians of the second and third grades. This method of determining the differences gives us a large number of direct measurements. Table XVII gives these sentence measurements of the intervals between the consecutive elementary grades.

TABLE XVII

P.E. INTERVALS SHOWN BETWEEN CONSECUTIVE ELEMENTARY GRADES BY EACH SENTENCE OF LANGUAGE SCALE A

Sentence No.	Interval II-III	Interval III-IV	Interval IV-V	Interval V-VI	Interval VI-VII	Interval VII-VIII
2 2x	1.229	.416	.196	-.154	.402	-.022
4 2y	1.381	.481	.486	.120	.262	-.171

56 13y				.508	.626	.676
Average . . .	1.425	.991	.671	.556	.576	.401

A general tendency will be noticed in Table XVII for the large differences between grades to appear in the harder sentences. I have grouped the measurements of each interval, putting in one group those measurements of the interval shown in Table XVII which were obtained from values lower than -1.5 P.E. in Table XV, in a second group those obtained from values

between -1.5 and 1.5 P.E., and in a third group those measurements obtained from positive values larger than 1.5 P.E. The average of each group of measurements for each interval is given below in Table XVIII.

TABLE XVIII

AVERAGES OF GROUPS OF DETERMINATIONS OF INTER-GRADE INTERVALS AS MEASURED BY SENTENCES OF LANGUAGE SCALE A

Group	Interval II-III	Interval III-IV	Interval IV-V	Interval V-VI	Interval VI-VII	Interval VII-VIII
Below -1.5	1.305	.448	.531	.378	.484	.236
-1.5 to 1.5	1.376	.929	.669	.537	.511	.339
Above 1.5	1.558	1.160	.724	.678	.756	.668

Table XVIII throws some very interesting light upon the question of how two grades differ in ability. Evidently one grade is better than the grade below both in the difficult and the easy tests, but the large differences are in the hard tests. An eighth grade child differs from a seventh grade child more distinctly in doing difficult tasks than in doing tasks that are moderately easy for both. At any rate, it appears that the child in the higher grade shows his superiority in doing harder tests rather than in doing the easy tests.

It hardly seems just to allow the intervals between grades to be influenced equally by sentences near the medians of the two grades concerned and by other sentences at the extreme ranges of the distributions. The sentences near the medians are more reliable measures and should probably be weighted, while those sentences which are more than 3 or 4 P.E. from the interval should possibly not be allowed to influence the measure of the interval at all, because at that extreme range caprice and accident have undue influence. It also seems unfair, in view of the facts shown in Table XVIII, to allow the easy sentences to have the same amount of influence as the more difficult in determining the intervals between grades. The plan that has been followed here has been to allow equal weight to all measures of the interval by sentences not more than 2 P.E. below the lower grade of the pair nor more than 4 P.E. above the higher grade of the pair

whose distance from each other is being measured. The average of the measurements by sentences in Table XVII, which lie within this range, are given below.

Grade Interval.	II-III	III-IV	IV-V	V-VI	VI-VII	VII-VIII
P.E. Interval.	1.408	.965	.705	.620	.606	.479

The intervals between the higher grades derived from the sentence locations given in Table XVI are shown in Table XIX, with the average of the determinations from sentences within the range -2 P.E. to $+4$ P.E.

TABLE XIX

56	.434	.437	.596	.188	1.106
Weighted Average	.556	.484	.265	.192	.813

¹ In each of the methods used to determine the intervals between consecutive grades, the difference between the eighth grade and the first year high school grade has been based upon the difference found in those school systems where both elementary and high school classes were tested.

Table XIX has the disadvantage of being based upon the small number of pupils tested in those school systems where both

elementary and high school grades were measured. Six sentences included in this group were also included in some tests given in three large city high schools, so that it is possible to get from them a measure of the differences between high school grades based upon a larger number of pupils, although upon a smaller number of sentences.

Table XX gives the score and P.E. equivalents for these six sentences in the high school grades.

TABLE XX

SCORE AND P.E. EQUIVALENTS FOR SIX SENTENCES IN THE HIGHER GRADES

Sentence No.	Grade IX		Grade X		Grade XI		Grade XII		Col. Grads.	
	Score	P.E.	Score	P.E.	Score	P.E.	Score	P.E.	Score	P.E.

55	124	1.777	190	1.065	293	.728	320	.316	149	-.585
54	53	2.447	101	1.702	142	1.531	157	1.227	136	-.362
No. tested. . . .	537		402		470		385		114	

The averages of the six determinations from Table XX of the intervals between grades, I have calculated to be as shown in the second line below.

	IX-X	X-XI	XI-XII	XII-C.G.
Language Scale A.	.484	.265	.192	.813
Six Sentences.	.538	.119	.329	.923
Average to use.	.511	.192	.260	.868

The third line shows the intervals which will be used as probably the most accurate determinations from sentences.

A second method of determining the intervals between grade medians makes use of the quartile as a measure of the P.E. If Scale A were perfect and if the surfaces of distribution in Figs. 8 to 14 were perfectly normal, the quartile, which is half of the range of the middle 50 per cent, would have been exactly the same as the P.E. Since we are assuming in the other determinations that completion-test surfaces of distribution are approxi-

mately normal, no great error will result from doing so in this case. I have therefore averaged the quartiles of each two consecutive grades and used this average as a divider of the crude score interval between the grade medians. Table XXI shows the result upon the data furnished by Table I.

TABLE XXI

DETERMINATION OF THE QUARTILE INTERVALS BETWEEN ELEMENTARY GRADES

	Grade II	Grade III	Grade IV	Grade V	Grade VI	Grade VII	Grade VIII
Median Score ...	4.5912	8.9864	14.3287	18.3888	21.9175	25.2719	28.0598
Quartile	2.0848	3.4127	4.1567	3.6140	3.6098	3.7496	4.0412
Score Interval	4.3952	5.3423	4.0601	3.5287	3.3544	2.7879	
Average Quartile	2.7487	3.7847	3.8858	3.6119	3.6797	3.8954	
Quartile Interval	1.5990	1.4115	1.0450	.9769	.9116	.7157	

Table XXII furnishes the same information regarding the quartile intervals between the higher grades, from the data given in Table III.

TABLE XXII

DETERMINATION OF THE QUARTILE INTERVALS BETWEEN HIGHER GRADES
(COMPLETE SYSTEM GROUP)

	Grade VIII	Grade IX	Grade X	Grade XI	Grade XII	College Gradu- ates
Median Score	27.8611	30.1470	33.6818	35.7272	37.1666	42.8125
Quartile	3.6882	4.2317	3.8992	3.3718	3.8437	2.8660
Score Interval	2.2859	3.5348	2.0451	1.4394	5.6459	
Average Quartile	3.9599	4.0654	3.6355	3.6077	3.3548	
Quartile Interval		.5772	.8695	.5626	.3989	1.6829

The third measurement of the differences between successive grades is also based upon the distribution of scores in Language Scale A. It will be observed in Table I that many second grade pupils received scores greater than the median score for the third grade, and that many third grade pupils received lower scores than the median second grade score. Between the third grade median, which is 8.9864, and the second grade median, which is 4.5912, there are (if we assume that the scores of the children recorded as making a given score are spread evenly over that step) 531.96 of the 1318 individuals in the second grade distribution and 545.58 of the 1437 individuals in the third grade distribution. In terms of percentages, 37.96 per cent of the third grade distribution and 40.36 per cent of the second grade distribution lie between the medians of these two grades. Each of these percentages is a percentage from the median of the distribution and may therefore be turned at once into a P.E. value by means of Table XIII. This transmutation reveals a difference between the medians of the second and third grades of 1.931 P.E. when measured by the second grade distribution, and 1.739 when measured by the third grade distribution.

It is also possible by this method to obtain certain indirect measures of the same distances. 47.66 per cent of the fourth grade distribution, for example, lies between the fourth grade median and the second grade median, so we may say (from Table XIII) that in so far as it is measured directly by the fourth grade distribution the second grade median is 2.948 P. E. below the median of the fourth grade. In the same way, 31.55 per cent of the fourth grade distribution lies between the median for that grade and the median for the third grade, which makes a P.E. difference of 1.332 between the two grades. From the median of the fourth grade distribution, then, we have found it to be 2.948 P.E. to the second and 1.332 P.E. to the third grade median, and by subtraction this gives us a difference between the second and third grade medians of 1.616 P.E.

It would be possible, of course, to derive indirect measures of each interval from any distribution of scores which covers the interval, but it would be unfair to allow these indirect measurements, especially those which are very near the extreme ranges of a distribution, to have the same influence as the direct measurements. Since the intervals have already been determined by

two other methods, it seemed best to give full weight here to direct determinations by this method and one-half weight to the indirect determinations obtained from the distribution next above the pair furnishing direct determinations and one-half weight to the indirect determination obtained from the distribution next below the direct pair.

Table XXIII gives for each elementary grade distribution the percentages of the distribution lying between its median and the medians of the two grades lower and of the two grades higher, and the P.E. equivalents of these percentages as taken from Table XIII.

TABLE XXIII

PERCENTAGES OF EACH ELEMENTARY GRADE DISTRIBUTION LYING BETWEEN ITS MEDIAN AND THE MEDIANS OF NEIGHBORING GRADES, WITH P.E. EQUIVALENTS

To Median of Grade	Percentages and Equivalents of Percentages of Distribution of							
	Grade II	Grade III	Grade IV	Grade V	Grade VI	Grade VII	Grade VIII	Grade IX
II		37.96% 1.739	47.66% 2.948					
III	40.36% 1.931		31.55% 1.332	46.70% 2.726				
IV	48.30% 3.146	30.45% 1.272		28.07% 1.148	40.82% 1.973			
V		43.43% 2.237	23.94% .951		23.62% .937	38.91% 1.812		
VI			39.33% 1.845	24.35% .970		23.13% .910	36.28% 1.621	
VII				40.15% 1.914	24.60% .982		19.14% .742	30.16% 1.257
VIII					37.82% 1.729	18.78% .726		13.04% .494

As indicated above, the direct determinations are given twice as much weight in this study as the indirect values, and the only indirect values used are those from the distributions immediately above and below the grades concerned. Table XXIV shows the values used.

TABLE XXIV

DETERMINATIONS OF THE INTER-GRADE INTERVALS OBTAINED FROM OVERLAPPING OF DISTRIBUTIONS OF SCORES ON LANGUAGE SCALE A

Determination	II-III	III-IV	IV-V	V-VI	VI-VII	VII-VIII

Average.....	1.7912	1.3335	1.0331	.9350	.9345	.7410

Table XXV gives data similar to Table XXIII but with reference to the higher grades in those schools where the entire school system was tested. The distributions of scores in Language Scale A upon which Table XXV is based will be found in Table III.

TABLE XXV

PERCENTAGES OF EACH HIGHER GRADE DISTRIBUTION LYING BETWEEN ITS MEDIAN AND THE MEDIANS OF NEIGHBORING GRADES, WITH P.E. EQUIVALENTS

To Median of Grade	Distribution of						
	Grade VII	Grade VIII	Grade IX	Grade X	Grade XI	Grade XII	Grade C.G.
VIII	17.12% .657		14.44% .549	36.03% 1.604			
IX	29.13% 1.203	16.29% .624		24.65% .984	32.65% 1.394		
X		35.49% 1.568	20.39% .795		16.04% .614	21.75% .853	
XI			31.32% 1.319	10.36% .389		9.13% .342	40.43% 1.938
XII				16.77% .643	7.23% .270		35.38% 1.561
C.G.					41.63% 2.047	33.92% 1.470	

The averages of the weighted direct values and the unweighted indirect values obtained from Table XXV, as illustrated in Table XXIV, are as follows:

Interval	VIII-IX	IX-X	X-XI	XI-XII	XII-C.G.
Average	.5853	.8803	.5068	.3091	1.5678

Half of the sentences in Language Scale A were included in a test given in two high schools where the elementary grades had not been tested. The sentences included in this high school test were selected, one sentence from each grade-pair in Scale A, so that the entire test had practically the same difficulty but was just half as long as Language Scale A. By going through the records and finding what score each student in the higher grades would have made if tested on these twelve sentences only, I was able to get a distribution of scores in each of these higher grades which had the advantage of larger numbers of pupils, although there were fewer sentences. Table XXVI shows the total dis-

No. tested	273	213	340	237	114
Median Score	15.14	16.78	17.74	18.26	21.69

tribution of scores made in this high school half-test by the pupils in Grade IX and above, whether they took it in the short form or as a part of Scale A.

From this table I have worked out the distances between grade medians in exactly the same way as they were derived above, with the following results:

Interval	IX-X	X-XI	XI-XII	XII-C.G.
Average	.6968	.3828	.2458	1.8054

As being probably the truest value for the intervals as determined by this method, I have taken the average of the determination by the small number of pupils with Scale A and the determination by the larger number of pupils with half of Scale A.

Interval	VIII-IX	IX-X	X-XI	XI-XII	XII-C.G.
From Scale A	.5853	.8803	.5068	.3091	1.5678
From half Scale A ..	.6968	.3828	.3828	.2458	1.8054
Av. Determination of Distributions..	.5853	.7885	.4448	.2774	1.6866

Values for the intervals between grade medians having now been worked out by three different methods, it is interesting to note that although the three determinations differ somewhat, their general characteristics are the same. It would be difficult to determine which method furnishes the best results. I have simply taken the average of the three results for each interval as the one to be used in this study. The results of each method and the average result are given in Table XXVII.

TABLE XXVII

THREE DETERMINATIONS OF THE INTERVAL BETWEEN SUCCESSIVE GRADES

Method	Interval Between Grades										
	2-3	3-4	4-5	5-6	6-7	7-8	8-9	9-10	10-11	11-12	12- C.G.

5. SELECTION OF A ZERO-POINT FOR COMPLETION-TEST ABILITY

Zero-points are absolute on some scales and arbitrary on others. It would be very hard to select a sentence so easy that to be unable to complete it would signify that one had absolutely no "language ability," so it will be necessary to choose an arbitrary zero-point for these tests if they are to be called "Language Scales." It will still be possible, however, to locate a zero-point which will represent absolute inability to complete any *printed sentence* as difficult as the easiest one used in the tests included in this study.

Reference to Table I shows that 255 of the 1318 children in the second grade made a score of 0 in Scale A, which means that they received no score at all. Between these children and the median of the second grade, however, there were 404 children, which is 30.65 per cent of all in the second grade. Reference to Table XIII shows that a difference of 30.65 per cent from the median of a normal distribution means a distance of 1.283 P.E. If this were our only evidence, therefore, we might locate our arbitrary zero-point at 1.283 P.E. below the median of the second grade.

Table I also shows that 19 of the 1437 pupils in the third grade made a score of zero, while 48.68 per cent scored above zero but below the median of their grade. This would locate the zero-point in Scale A at 3.291 P.E. below the third grade median. We have already determined (Table XXVII) that the third grade median is 1.599 P.E. above the second grade median. The zero-point in Scale A is therefore located by the third grade distribution at 1.692 ($3.291 - 1.599 = 1.692$) P.E. below the second grade median.

The median score of the second grade on Language Scale A is shown by Table I to be 4.5912, and the quartile 2.0848. Assuming that the quartile is equal to the P.E., as it is in a perfectly normal surface of frequency, we find by dividing the score by the quartile that the second grade median is 2.2022 P.E. above zero.

The median score of the third grade is shown by Table I to be 8.9864. Table XXI shows the average of the quartiles of grades II and III to be 2.7487. Dividing the score by this average of the quartiles places the third grade median at 3.2693 P.E. above zero. From this determination, then, zero would be 1.670

(3.269 - 1.599 = 1.670) P.E. below the second grade median. This makes the fourth determination of the distance from zero to the second grade median. The four determinations are as follows:

From the second grade distribution.....	1.283
From the third grade distribution.....	1.692
From the second grade score.....	2.202
From the third grade score.....	1.670
Average.....	1.712

It would be very convenient in any scale for ability of any sort to have at least one test located exactly one unit above the zero-point. The easiest sentence in Scale A is shown by Table XV to be sentence No. 4, "We are going.....school."

After accepting tentatively the determination just made that the second grade median is 1.712 P.E. above the zero-point, the location above zero of sentence No. 4 was worked out according to the scheme to be described below. It was found that, under these conditions, this sentence No. 4 had a value of 1.018 above zero. This was so near 1.000 that it was decided to employ such a value for the distance between zero and the second grade median as would place sentence No. 4 exactly at 1 P.E. above zero. 1.687 P.E. was found to be such a value. This is only .025 P.E. smaller than the average of the four determinations made above and is probably just as near the true distance.

For the purposes of this study, then, zero will be defined arbitrarily as 1 P.E. below sentence No. 4, or as 1.687 P.E. below the median of the second grade distribution shown in Table I.¹

Having located our zero-point at 1.687 P.E. below the second grade median, and having previously determined the distances between the medians of each consecutive grade, it is now an easy

¹ It must be borne in mind that this is not a zero-point for language ability or even for completion-test ability, but merely the zero-point for ability to complete the printed sentences used in this study. The zero-point for ability to complete a spoken sentence would probably be found several units below the zero-point used in this study. The absolute zero-point for ability to complete the easiest possible incomplete idea or representation of an object would probably be found still further down on an absolute scale, below even the zero-point for ability to complete a spoken sentence. If scales are ever constructed for these simpler forms of completion test, we may expect the zero-point established in this study to be located several units above the zero-point for these simpler tests.

matter to calculate the distance of each grade above zero. These distances are shown in Table XXVIII.

TABLE XXVIII

DISTANCES ABOVE ZERO OF THE MEDIANS OF EACH SCHOOL GRADE. 1 = P.E.

Grade	Above Zero	Below Next Grade
II	1.687	1.599
III	3.286	1.237
IV	4.523	.928
V	5.451	.844
VI	6.295	.817
VII	7.112	.645
VIII	7.757	.573
IX	8.330	.723
X	9.053	.400
XI	9.453	.312
XII	9.765	1.412
C.G.	11.177	

Fig. 17 (page 55) represents the relations of the grade medians to each other, to the zero-point, and to the distributions of other grades, upon the assumption that ability in each grade is distributed in accordance with the normal surface of frequency, and that the values given in Table XXVIII are substantially correct.

6. REFERRING ALL SENTENCES OF SCALE A TO ZERO

Table XV gave the value of each sentence of Language Scale A for each elementary grade, and Table XVI gave their values for the higher grades. In Table XV, for instance, sentence No. 7 had a positive value of 1.154 in the second grade and a value of $-.203$ in the third grade. Now we know from Table XXVIII that the second grade median is at 1.687 P.E. and the third grade median at 3.286 P.E. above zero. 1.154 added to 1.687 gives this sentence a value of 2.841 above zero in the second grade, while .203 subtracted from 3.286 gives it a value of 3.083 above zero in the third grade. Table XXIX (page 56) is made from Table XV by employing in this way the values given in Table XXVIII for each grade median.

FIG. 17. Relations of Grade Distributions to Each Other.

Table XXX shows the location above zero of each sentence in Language Scale A for each higher grade in the schools where both elementary and high school classes were tested. Table XXX is derived from Table XVI by employing the grade locations shown in Table XXVIII.

The number of pupils in each of the higher grades which furnished the data for Table XXX was small, and yet these pupils were slightly more able than the pupils in the same grades of the large city high schools where a short completion test was given. This means, probably, that for high school students in general the values assigned in Table XXX are too low.

Six of the sentences actually were included in both sets of tests, and the location of each of these six sentences for each of the higher grades was shown in Table XX. Table XXXI gives the

TABLE XXX

location above zero of each of the six sentences for each high school grade, first as calculated from Table XXX, and second as determined from the larger number of pupils reported in Table XX. Table XXXI also shows the amount of difference between the two values for each sentence and the average amount of difference caused by the larger numbers from the city high schools.

In order to correct the values shown in Table XXX for the slightly extraordinary abilities of the pupils from whom it was

TABLE XXXI

CHANGES IN VALUES ABOVE ZERO OF SIX SENTENCES BY USE ON LARGER NUMBERS OF HIGH SCHOOL STUDENTS

derived, .09 was added to all values for grade IX, .07 to all grade X values, .15 in grade XI, and the values in grade XII were not changed at all. These corrections were determined by reference to the average differences shown in Table XXXI.

Having now located by each grade the distance above zero for each sentence of Scale A, we may undertake to determine what the location of each sentence is for school children in general. It will be noticed in Table XXIX that there is a tendency for each sentence to have a higher location in the higher grades than it has in the lower grades. This is probably due in part to the presence in these higher grades of a few inferior individuals, who fail to make satisfactory completions of sentences which should be easy for them. It would be unjust, however, to allow the few dull pupils who manage to get into the higher grades to keep on dragging these easy sentences into the higher ranges of the scale. Undoubtedly the most reliable distribution for determining the general difficulty of a sentence is the distribution whose median is

nearest to the position of the sentence. I have therefore given double weight to the determinations by those grade distributions whose medians were not more than 1 P.E. from the sentence's location, and single weight to all determinations by grades more than 1 P.E. but less than 2.5 P.E. from the sentence.

Fig. 18 shows how a grade distribution would affect sentences at various distances.

FIG. 18. Showing the Influence Allowed Various Parts of a Distribution in Determining the General Location of a Sentence.

The determination of a distribution is given double weight if its median is within 1 P.E. of a sentence, single weight if more than 1 and less than 2.5 P.E., and no weight at all in the general determination if its median is more than 2.5 P.E. from the sentence. Areas *a* and *f* are not allowed to help determine the general difficulty of a sentence.

Table XXXII shows for the first five sentences the details of just how the weighting was done.

TABLE XXXII
DETERMINATION OF GENERAL LOCATIONS OF SENTENCES

Distribution	Sentences No.				
	2	4	7	11	22
II	.985 .985	.928 .928	2.841	2.855	3.948
III	1.355	1.146	3.083 3.083	3.058 3.058	4.293
IV	2.176		3.437	3.392	4.276 4.276
V			3.669	3.575	4.255
VI			3.915	3.930	4.529
VII					
Average	1.376	1.000	3.338	3.311	4.263
Use	1.38	1.00	3.34	3.31	4.26

Weighting in this manner the values shown in Tables XXIX and XXX (after raising the values of Table XXX by the amounts determined in Table XXXI), the figures obtained to show the general difficulty of each sentence for all grades are shown in Table XXXIII.

TABLE XXXIII
FINAL VALUES OF SENTENCES IN SCALE A

Sentence No. ¹	General Value
4	1.00

55	10.19
54	10.76
56	11.17

¹ Sentences are here in the order of difficulty, not the order of Scale A.

7. ESTIMATION OF THE DIFFICULTY OF OTHER SENTENCES¹

Scale A is the basis upon which all values are built in this study. The Graded Series of test sentences was given to a smaller number of children and was not given to the College Graduate group, so there are two corrections to be made in the figures obtained directly from its use: a correction must first be made for any difference in the abilities of the groups which are called by the same grade number, and a second correction must be made in the values of the more difficult sentences for the lack of the College Graduate group. The other lists of tests outside of the Graded Series require the same corrections, except that in the cases of these others the second correction is not simply for the lack of one grade group but for the lack of several such groups.

Lack of sufficient numbers of children tested to actually locate the difficulty of a test can not be corrected, except by testing a sufficient number of children. The writer feels that the irregularities due to small numbers are negligible in the sentences of Scale A, very small in the other sentences of the Graded Series, somewhat larger in the sentences numbered from 57 to 72, and still larger in those sentences numbered higher than 72. For the sentences numbered above 56, it can only be said that their difficulty has been estimated carefully, although much more statistical labor has been spent upon them than upon the sentences of Scale A. To actually measure the difficulty of a sentence requires that it be tried upon hundreds of children in each grade. No amount of calculation can take the place of large numbers of children tested.

Table XXXIV gives the score made upon each sentence of the Graded Series in each school grade. Table XXXV gives the P.E. equivalents of the score, and Table XXXVI gives the resulting location above zero of each sentence.

¹Other sentences than those included in the Language Scales are not given in the body of this report, but each sentence used in this investigation, together with the scheme used in scoring it, will be found in the Appendix.

TABLE XXXIV

The corrections for the results of the Graded Series, to compensate for the low ability shown by those who were tested with the entire Graded Series as compared with those tested by Scale

A only, are determined from Table XXXVII, which shows the differences, for each sentence of Language Scale A, between the results obtained in the Graded Series alone and the results obtained from all pupils who were tested with the sentences of Language Scale A. Table XXXVII is obtained by taking the difference on each sentence between the values shown in Table XXXVI and those shown in Tables XXIX and XXX.

TABLE XXXVII

The changes indicated in Table XXXVII are not averaged as they were in the case of Table XXXI, but are grouped according to the nearness of the median of the distribution concerned to the sentence in question. All changes upon sentences more than 1 P.E. below the median are put into one group, all those upon sentences from 1 P.E. below to 1 P.E. above are put into another group, and those upon sentences more than 1 P.E. above are put into a third group, and each group is averaged. The averages of the groups are then used to correct the values of the

sentences which were not given in Scale A, the corrections being applied within the same limits as were used in obtaining them. The result of employing these average changes as corrections is shown in Table XXXVIII.

The general difficulty of the Graded Series tests was calculated from Table XXXVIII in exactly the same way as the general values of the sentences in Scale A were calculated from Tables XXIX and XXX.

The amount of compensation for the lack of the College Graduate group was determined by finding what the value of the more difficult tests in Scale A would have been if the values from this superior group had not been used in calculating the general difficulty of the sentences. It was found that the College Graduate group had not influenced the general value of any Scale A sentence receiving a general value of less than 6.00 P.E. The

sentences which without the C.G. group would have been located between 6.00 and 7.00 had been raised on the average .16 P.E. by the use of the C.G. group. Those sentences which had received between 7.00 and 8.00 had been raised .13; between 8.00 and 9.00, .08; between 9.00 and 10.00, .07; and above 10.00, .07. These averages were therefore applied as corrections to the general determinations for the Graded Series sentences, each average being applied to the range within which it had been found.

The final values obtained after all the corrections had been made are shown in Table XXXIX.

TABLE XXXIX

FINAL VALUES OF SENTENCES GIVEN IN THE GRADED SERIES ONLY

Sent. No.	Value

¹ Some children did not have a chance to complete the sentences on the last page as their attention was not called to the fact that it contained sentences.

The remaining lists of tests were treated in the same manner as the Graded Series. The corrections to be made for differences of ability were derived by examining the behavior of the sentences of Language Scale A, which were always given with the new sentences in order to obtain just these comparisons. Corrections for the lack of grade groups were made by finding what would have happened if these grade groups had not been used in making up from Tables XXIX and XXX the final measure of the difficulty of the sentences of Scale A.

The following tables give merely the score made on each sentence, the number of pupils tested, and the final position assigned to the sentence.¹ In those cases where a sentence appeared in two different lists and therefore has two estimates of its final position recorded in the following tables, it will be well in practice to make use of the arithmetic average of the two determinations.

72	7.55

¹ To show here the individual steps taken with each group of sentences would require the printing of an enormous quantity of statistical tables and would add nothing to the value of this study. The same methods and the same care were employed to secure accurate results as in the case of the sentences of the Graded Series. Publication of the scores made on these sentences will make it possible for other investigators to use my results in any way that may seem desirable.

APPENDIX

APPENDIX

1. CORRELATIONS

The writer of this monograph has not as yet undertaken a systematic study of the correlations shown by the language scales presented here. Such a study needs to be made, however, before it will be possible to say just how these tests are related to other tests of knowledge and ability. Such correlations as are reported here have been worked out incidentally, sometimes as a matter of curiosity and sometimes in connection with other studies. They are reported here merely to show the need that exists for further investigation.

Simpson,¹ who made a very thorough investigation of the correlations of intellectual tests, including the paragraph completion test, which he calls the Ebbinghaus test, has this to say with regard to the reliability of the completion test (p. 48): "Test XIV, Ebbinghaus mutilated test, was very high in reliability as used, easily the highest of all. The coefficients of correlation between the two halves of the test are: .96 for the Good, .93 for the Poor, and .92 for all together. It is beyond question a good test, and should be perfected and standardized, with a considerable number of specimens graded in difficulty."

Simpson estimates (p. 63) the true correlation between the Ebbinghaus test and the other tests used in his study as follows: Ebbinghaus test correlates with Hard Opposites .85, with Memory of Words .82, with Easy Opposites .72, with A Test .54, with Memory of Passages .71, with Adding .65, with Geometrical Forms .36, with Learning Pairs .60, with Completing Words .60, with Drawing Lengths .15, and with Estimating Lengths .33. His corrected coefficient for the correlation between the Ebbinghaus test and Estimated Intelligence is .89 (p. 75).

The Language Scales proposed in this report differ somewhat from the paragraphs used by Simpson in his study, and the correlations he has reported would probably not apply exactly to the tests used in this study. Although the writer is inclined to believe that the sentence tests are more accurate and that the correlations with them will be even higher than those shown with the paragraph tests, a thorough study of the correlations of the sentence tests is the only way in which this belief can be proved or disproved. Such a study will undoubtedly be made very soon. In the meantime the following results are suggestive of the sort of correlations we may expect.

In an unpublished study of the mental abilities of dependent children in certain institutions,² the "preliminary list" of completion-test sentences mentioned on page 4 was given, along with the Binet-Simon tests, the Stenquist

¹ B. R. Simpson: *Correlations of Mental Abilities*. Teachers College Contributions to Education, New York, 1912.

² Since the above section was written, this study has been published in the *Archives of Psychology*, No. 33, Sept., 1915. J. L. Stenquist, E. L. Thorndike, and M. R. Trabue: *The Intellectual Status of Children who are Public Charges*.

tests of mechanical construction ability, and certain other tests. Before sending in the report of the results, the writer worked out a few coefficients of correlation¹ with two groups of children. In a group of 50 boys and girls, ages 10-16, the completion-test sentences gave a coefficient of .74 with the Binet tests, and .46 with the Stenquist test, which showed a coefficient of .62 with the Binet test. With a group of 39 boys, ages 10-16, the results were as follows:

Completion tests with Binet tests,	$r = .85$
Completion tests with Stenquist tests,	$r = .59$
Stenquist tests with Binet tests,	$r = .58$

In a certain seventh grade class of 30 children, in which some of the graduate students at Teachers College made a number of tests, Language Scale A made coefficients as follows:

with English Composition (Hillegas Scale),	$r = .72$
with Courtis Problems in Division,	$r = .04$
with Thorndike's Reading Scale Alpha,	$r = .47$
with Thorndike's Reading Scale A,	$r = .49$

In the sixth grade of 33 pupils, where the writer gave a number of tests, the results were as follows:

Language Scale A	
with teacher's estimate of intelligence,	$r = .74$
with Woody Multiplication Test,	$r = .51$
with Courtis Multiplication Test,	$r = -.12$
with Thorndike's Scale Alpha,	$r = .47$

In a second sixth grade of 29 pupils, the results of certain tests were combined and the correlation worked out between the combined scores and the scores in Language Scale A. The results were as follows:

Language Scale A	
with Combination of all marks made in one semester at school,	$r = .49$
with Combination of Thorndike's Scale Alpha, Buckingham's Spelling Scale, and Hillegas's Composition Scale,	$r = .58$
with Combination of Vocabulary Test, Opposites Test, Mixed Relations Test, and Proverbs Test,	$r = .39$

As indicated above, these coefficients are not numerous enough or reliable enough to prove anything conclusively. They do suggest, however, that there is a positive and rather intimate relation between ability to complete sentences and ability in other tests of language and general intelligence.

¹Since there was good evidence that none of the tests used were evenly graded as to difficulty, it seemed best to use Spearman's formula, which takes into account only the relative positions of the individuals in the different tests. This formula, which is given on page 168 of Thorndike's *Mental and Social Measurements*, is as follows:

$$\rho = 1 - \frac{6 \sum D^2}{n(n^2 - 1)}$$
 The ρ values are then converted into r values by means of the table given by Thorndike, which shows the r value for each possible ρ value as derived from the formula

$$r = 2 \sin \left(\frac{\pi}{6} \rho \right).$$

One rather surprising correlation has been reported to me by Professor W. D. Scott, of Northwestern University. Thirty efficiency experts employed by a large industrial concern in New England were tested by Dr. Scott, who used ten different tests, including a list of completion-test sentences prepared by the writer. Each member of the firm who knew the thirty experts made a list of them, arranging them in order according to his judgment of their efficiency as efficiency experts. Professor Scott mailed a list of the men, ranked according to the results of his ten tests, and on the same day the members of the firm mailed their lists to him. Professor Scott's combined results gave a coefficient of .87 with the combined judgment of the employers. The completion test, which was only one of the ten tests, had a coefficient of .64 with the employers' combined judgments, and with the combined result of all ten tests, $r = .69$.

2. SCHEME FOR SCORING SENTENCES

The question of what should be called correct and what should be called incorrect in scoring the sentences as completed is a question upon which a great deal of time and worry may be spent. The important thing about scoring the sentences, however, is not that the scheme used shall be absolutely perfect, but that the scheme used shall be used consistently.

These sentences might be used to measure a great variety of qualities in the individual completing them. For example, we might score altogether according to the correctness of the grammatical forms used. On the other hand, we might ignore grammar altogether and make these sentences test the child's understanding, scoring according to the child's grasp of the ideas suggested by the printed words. We might score according to the judgment shown or the truthfulness of the child's statements in the sentences as completed. Again, it might be possible to use these sentences as tests of memory for phrases, of richness of associations, of unity and clearness of expression, of aptness in the choice of words, of imagination, or of other characteristics.

The scheme that has actually been used has not been any particular one of the above possibilities, but simply a general combination of all of them. In some cases one element may have predominated in causing a decision, and in other cases another element. No one needs to follow the scheme shown below if he finds it wrong, for it is only given in order that it may be perfectly clear just which combinations were allowed and which were not allowed in this study. The important things for one to do are to be sure that he is making no great errors in judgment, to be consistent, and to report just how he did score each sentence. The writer suggests that the detailed scheme shown on the following pages be used as it stands in so far as possible, in order to secure uniformity and comparability.¹

¹With the preliminary series, 5 points were given for perfect, 4 for slightly less than perfect, 3 for still less, etc. The present scheme (2-1-0) is practically the same as though the lower end of the older scheme (5-4-3-2-1-0) had been omitted, using 2 in place of 5, 1 in place of 4, and 0 in place of 3, 2, 1 and 0. With 40 pupils in each grade, the correlation between the relative difficulty of the preliminary-list sentences in the 6A grade and their relative difficulty in the 8B grade was .965 by the 5-0 method, .962 by the 2-0 method now used, and .958 if everything now scored 2 and 1 were called "right," and everything else "wrong."

The following general scheme has been the basis upon which the more detailed judgments have been based:

GENERAL SCHEME

Score 2

A score of 2 points is to be given each sentence completed perfectly. Errors in spelling, capitalization, and punctuation should not be allowed to affect the score.

Score 1

A score of 1 is to be given each sentence completed with only a slight imperfection. A poorly chosen word or a common grammatical error, which makes the sentence less than perfect and yet leaves it with reasonably good sense, should serve to reduce the score from 2 to 1.

Score 0

A score of 0 is to be given if the sentence as completed has its sense or construction badly distorted. A sentence must have reasonably good meaning and express a sentiment which might honestly be held by an intelligent person in order to receive a higher credit than zero.

DETAILED SCHEME

In those sentences having only one blank to be filled, any word appearing under the heading *Score 2* was considered entirely satisfactory as a completion of the sentence. Those words appearing under the heading *Score 1* were given half credit—a score of 1—while the words appearing under *Score 0* were given a score of 0. The score of each sentence should be written on the test paper just under or at the end of the sentence.

In those sentences where more than one blank appears, the different groups of words appearing below are arranged in their proper order and are connected by a dotted line to show the proper sequences: the first group on the left hand side of the page being words for the first blank in the sentence, and the dotted line showing what words are used in the next blanks to make up a combination of the value shown by the heading *Score 2*, *Score 1*, or *Score 0*, as the case may be. The commas are used merely to separate the fillers for the same blank and are not a part of the completion. An asterisk following a bracketed group of words indicates that this group of words will be indicated thereafter by an asterisk alone. Double asterisks, triple asterisks, etc., are also used to refer to and stand for entire groups of words. This device obviates the necessity of repeating an entire list of words for each combination in which the list may be used.

The lists given in the following pages are not exhaustive, but they are suggestive of the way the scoring has been done. In many cases a different tense of the same word has not been recorded. Anyone who uses this scheme will be called on constantly to make judgments upon new combinations.

3. CALCULATION OF MEDIAN SCORE IN LANGUAGE SCALES

Each child who spends the allotted amount of time in an attempt to complete the sentences of any of the language scales described in this study should be given as a total score the sum of the number of points made upon the individual sentences contained in the scale. For example, the child who completes perfectly the first three sentences of Scale B, and almost perfectly the fourth sentence in this scale, should be given a total score of seven points on Scale B. ($2+2+2+1=7$.)

To find the ability of the class, it will be necessary to take into consideration the total score made by each child in the class. A distribution should therefore be prepared showing the scores made by the individual members of the class. This distribution should indicate the number of pupils in the class who make a score of zero, the number making a score of one, the number making a score of two, the number making a score of three, and so on for each step up to twenty, the highest possible score in Scales B to E. As examples of this sort of distribution, we may take the following:

Number of Times Each Score Was Made in Language Scale C

Score	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
Group X	.	3	5	8	4	3	2	2	.	1	.	.	.	.	.	.	.	.	.	.
Group Y	.	.	.	1	.	2	3	5	6	4	3	2	1	2	.	.	.	.	.	.
Group Z	.	.	.	.	.	.	.	.	2	2	3	5	4	.	6	3	4	2	1	.

There are 28 individuals in Group X, 29 individuals in Group Y, and 32 individuals in Group Z. The only adequate comparison of these three groups is such a table as that shown above, or a surface of distribution representing the same facts. The average score, or even the median score, is in itself inadequate as a measure of the group, although it is usually desirable to calculate the median as an indication of the central tendency of the group's ability.

The median of any distribution is that point on the scale which divides the distribution into two exactly equal parts. When the scales are very crude, and measurements of small numbers of individuals are being considered, it is not worth while to locate the median point any more accurately than by indicating upon what step of the scale it falls. In the case of carefully derived scales, however, it is often desirable, especially where the group to be measured is reasonably large, to locate the exact point within the step where the median falls. This median point in the case of the scales here presented may well be calculated to the tenth, or even to the hundredth of a unit, if 200 or more individuals are in the group being measured.

Since there are 28 individuals in Group X of the distributions shown above, the median point will evidently fall between the fourteenth and the fifteenth individuals. If we begin with the three individuals making a score of 2, and

count up through the five individuals making a score of 3, we should have to count out six of the eight individuals making a score of 4 in order to arrive at the point upon each side of which an equal number (14) of papers were scored.

It now becomes necessary to define the fourth step. Some of those scored four may have been worth just barely 4 points, while others of this group may have been worth almost 5 points. It is impossible, of course, to know at just what points between these two extremes each of the eight individuals was located. The best single assumption to make, and the one which should always be made, is that those individuals scoring upon any single step of a scale are distributed along the step at equal distances from each other. We may therefore assume that the eight individuals scored upon step 4 range from 4.0 to 4.999 and lie at equal distances from each other along this range.

If we count out six, therefore, of the eight individuals who scored on step 4, we shall arrive at a point which is approximately 4.7. 4.7 is therefore the median point of Group X.

Similarly there are 29 individuals in Group Y. The middle case is the fifteenth individual, who is the fourth of the six scored on step 9. This individual has fourteen persons scored above him in ability and fourteen persons scored below him in ability. The median point, therefore, will lie at the middle of that fraction of the step assigned to him. In order to reach this point it will be necessary to count out three and a half of the six individuals scored on step 9, which brings us to 9.6, the median of Group Y.

Group Z presents a peculiar problem in the calculation of its median. There are 16 individuals above score 14, and 16 individuals below score 14. Probably the wisest assumption to make is that the four individuals scored on 13 take up all of the thirteenth step and that the six individuals scored upon 15 take up all of that step. If this is assumed, the median falls upon step 14, probably at 14.5, since any given distance on a scale is best represented by its middle point.

The 25 percentile and the 75 percentile are to be found in a manner similar to that for finding the median, counting into the distribution one-fourth of the total number of cases for the first, and three-fourths of the total number of cases for the second.

4. TENTATIVE STANDARD SCORES IN LANGUAGE SCALES B, C, D, AND E

The new scales proposed in this monograph have not as yet been employed upon a sufficiently large number of children in each grade to establish any definite standards of attainment. Although each sentence has been well tested in other combinations, the scores that will be obtained with the new scales can only be estimated. It seems worth while, however, especially for Scales B, C, D, and E, which will probably be employed somewhat more generally than the four special-type scales, to indicate in a general way what results may be expected in each school grade. The writer therefore gives below the best esti-

mate¹ he is able to make of the median score that any given school grade should make on one of these four scales.

Grade	Median
II	3.0
III	6.0
IV	8.0
V	9.6
VI	11.0
VII	12.3
VIII	13.3
IX	14.2
X	15.3
XI	15.8
XII	16.2

The above tentative standards will not be found to be exact for any given scale, but until we have accurate results from a large number of applications of each scale in each grade, the above figures may be used as the best estimate available for any one of the four scales. On the whole it may be said that the above estimates are more likely to be too low than to be too high. One may also expect the same class or classes of equal ability to make a median score from .4 to .8 of a point lower in Scale C than in Scale B, while the median on either Scale D or Scale E will probably fall between that obtained on Scale B and that obtained on Scale C.

With a view to establishing more accurate standards of attainment, the writer will be pleased to receive copies of the results obtained by any investigator employing any of the scales proposed in this monograph. If anyone, having five hundred or more public school pupils to measure, is willing to coöperate to the extent of reporting to the writer the score of each child on each sentence of the scale used, the writer will be glad to send him blanks for making such records and to refund 10 per cent of the purchase price of the scales (as purchased from the Teachers College Bureau of Publications) immediately upon receipt of such reports.

¹In making this estimate it is of course assumed that anyone who wishes to compare their results with these figures will make the tests carefully as directed on pages 20 to 22 of this monograph, employing the blanks furnished by the Teachers College Bureau of Publications, and scoring each sentence according to the scheme given in Section 2 of this Appendix. Any deviations from this procedure should not be made without making allowances for differences in the results.
